Abstract
Four hundred (400) high vaginal swabs (HVS) were carefully and aseptically collected from symptomatic and asymptomatic pregnant and non-pregnant women aged 18-49 years. The samples were analyzed using standard microbiological methods. Wet preparation of the samples were examined microscopically and the swabs were cultured on Sabouraud Dextrose Agar (SDA) plates and incubated at 37°C for 3-4 days. The overall prevalence of *Candida albicans* was 137 (34.25%). Among this number, 96 (36.36%) of the symptomatic women had *Candida albicans* while 41 (30.14%) asymptomatic women also had *Candida albicans*. This investigation recommends good personal hygiene and regular checkup for women domiciled in this area since *C. albicans* poses a major health challenge to avoid complicated health problems.

Keywords: *Candida albicans*, asymptomatic, prevalence, candidiasis.

1. INTRODUCTION
The genital tract is the portal of entry for numerous sexually and non-sexually transmitted diseases. Different kinds of bacterial and non-bacterial infections exist that affect the female reproductive tract and cause vaginal discharge. Vaginal discharge is a common symptom in primary health care and is often the second most common gynecological problem after menstrual disorders. Most women regard any secretion from the vagina as abnormal discharge and the first task for primary health care providers is to ascertain whether it is pathological or physiological. There are few women who complain of vaginal discharge, discomfort or odour without any objective finding (Dodson and Friedrich, 1997). *Candida albicans* is the most frequently isolated invasive fungal pathogen in humans, with the majority of infections being localized to the urogenital or oropharyngeal tracts of the patient (Fidel, 1996). In addition to localized infections, *Candida albicans* is also able to establish a systemic infection in its host.

Vaginal candidiasis is a common gynecological problem among women of child bearing age worldwide (Anderson et al; 2004; Naglik et al; 2003). It has been reported that up to 75% of sexually active women will have experienced symptomatic vaginal candidiasis (Schroppei et al; 1994; Lisiak et al; 2003). *Candida* species are part of the lower genital tract flora in 20-50 % of healthy asymptomatic women (McClelland et al., 2009; Akah et al., 2010). It is reported that carrier rates are higher in women treated with broad spectrum antibiotics (Singh, 2003), in pregnant and diabetic women (Donders, 2002; de Leon et al., 2002) and women with HIV/AIDS (Reed et al., 2003; Duerr et al., 2003; Akah et al., 2010). *Candida albicans* is both the most frequent colonizer and is responsible for most cases of vulvo vaginal candidiasis (Singh, 2003).

Several factors can be associated with increased rate of vaginal colonization by *C. albicans*: these include pregnancy, use of high oestrogen content drugs and oral contraceptives (Akah et al., 2010; Alli et al., 2011), uncontrolled diabetes mellitus (CDC, 2002; Alli et al., 2011), prolonged use of broad spectrum antibiotics (Mardh et al., 2002; Alli et al., 2011) which kill the good and beneficial bacteria, allowing yeast overgrowth, poor dietary habits and poor personal hygiene. Many practitioners believe that nylon underwear and tight insulating clothing predispose to vaginal candidiasis by increasing the temperature and moisture of the perineum (Nwankwo et al., 2010; Alli et al., 2011). A study among African women wearing tight clothes reported a higher prevalence of *Candida albicans* in Vulvovaginal candidiasis than those wearing loose clothing (Alli et al., 2011). The aim of this research work was to determine the prevalence of *candida albicans* among women attending Federal Medical Centre Asaba South-South, Nigeria.

2. MATERIALS AND METHODS
2.1 Collection of samples
Four hundred (400) high vaginal swab (HVS) specimens were collected from both symptomatic and asymptomatic pregnant (300) and non-pregnant (100) attending Federal Medical Centre Asaba using sterile swab sticks. The characteristic features of the symptoms include foul smelling odour, vaginal discharge (scanty or purulent), burning sensation and pain during urination, as well as itching and irritation of the vagina. The samples were labelled appropriately and taken to the laboratory immediately for analysis.
2.2 Microscopic Examination of Samples

About 1 ml of normal saline was put in the tube containing the swab to cover the cotton bud, shaken and allowed to stand for some minutes. A drop of this was placed on a clean grease-free slide and was viewed with low power objectives (10× and 40×) for yeast cells. Germ tube test was also carried out on suspected yeast colonies and positive colonies were sub-cultured onto corn meal agar medium for further identification by the formation of chlamydiospore by C. albicans.

2.3 Microbiological analysis

All the specimens were streaked on prepared Sabouraud Dextrose agar (SDA) plates. The plates were incubated at 37°C for 3-4 days. Colonies were sub-cultured on MacConkey agar to obtain pure cultures. Colonial morphology, gram staining and biochemical reactions were used to identify the isolated organisms.

3. RESULTS

Table 1: Prevalence of Candida albicans among pregnant and non pregnant women.

<table>
<thead>
<tr>
<th>Status</th>
<th>No examined</th>
<th>Candida albicans (%)</th>
<th>Non-albicans (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pregnant women</td>
<td>300</td>
<td>120 (40%)</td>
<td>21 (7%)</td>
</tr>
<tr>
<td>Non pregnant women</td>
<td>100</td>
<td>17 (17%)</td>
<td>6 (6%)</td>
</tr>
<tr>
<td>Total</td>
<td>400</td>
<td>137 (34.25)</td>
<td>27 (6.75%)</td>
</tr>
</tbody>
</table>

Out of 300 pregnant women who were examined, 120(40%) had Candida albicans which was higher than the non pregnant women 17(17%) (Table 1).

Fig 1: Distribution frequency of Candida albicans in different trimester of pregnancy

Figure 1 shows the frequency of Candida albicans at different trimester of pregnancy with the highest at the third trimester 57(47.5%) followed by second trimester 51(36.95%).

Table 2: Prevalence of Candida albicans among symptomatic and asymptomatic women

<table>
<thead>
<tr>
<th>Status</th>
<th>Number examined</th>
<th>Candida albicans (%)</th>
<th>Non-albicans (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Symptomatic</td>
<td>264(66)</td>
<td>96 (36.36%)</td>
<td>18(6.81%)</td>
</tr>
<tr>
<td>Asymptomatic</td>
<td>136(34)</td>
<td>41 (30.14%)</td>
<td>9 (6.61%)</td>
</tr>
<tr>
<td>Total</td>
<td>400(100)</td>
<td>137 (34.24)</td>
<td>27(6.75%)</td>
</tr>
</tbody>
</table>

In table 2, C. albicans of the symptomatic women 96(36.36%) was higher than the asymptomatic 41(30.14%) women.
From figure 2, it becomes imperative that age 20-29 had the highest prevalence of *Candida albicans* with 77(38.5%), followed by ages 30-39 with prevalence of 50(33%) and the least was ages 40-49 with prevalence of 2.

Table 3: Prevalence of *Candida albicans* in women who use antibiotics

<table>
<thead>

<td>27 (6.75%)</td>
</tr>
</tbody>
</table>

Table 4 showed the prevalence of *C. albicans* 90(40%) in women wearing synthetic underwear is higher than those wearing cotton 47(26%).

4. DISCUSSION

In this study, the result showed that out of 400 women, 137(34.25%) showed positive result for *C. albicans*. This 34.25% observed in this study corroborates the works of (Singh, 2003; Akah et al., 2010; Alli et al., 2011) which stated that *Candida albicans* is the most frequent colonizer as well as responsible for most cases of vulvovaginitis. This prevalence of *Candida albicans* (34.25%) was higher compared to that reported by Choudhry et al. (2010) to be 2.0% in their study. It was also higher than the 2.20% reported by Konje et al. (1991) in Ibadan and 22.1% reported by Anorlu et al (2004) among women in Lagos University Teaching Hospital (LUTH), Nigeria. However, it was lower than the 60.0% reported for *C. albicans* infection among pregnant women by Alli et al. (2011) and the 40.0% reported by Oyewole et al. (2010) among non-HIV infected women in Sagamu, Ogun state, Nigeria. The prevalence among pregnant (40%) was higher than non pregnant women (17%). This result supports the findings of Newman et al. (1975) who demonstrated increased number of positive microscopic findings in pregnant women (40.9%, 83/203), compared to (23.8% 58/244) in non-pregnant women and that of Enweani et al. (2001) which showed a greater percentage of the vaginal yeast detected in pregnant women (51.5%, 203/394), compared to non-pregnant women (40.6%, 43/106). This confirms that pregnancy could be a risk factor which increased the possibility of vaginal candidiasis. The high prevalence in this study among pregnant women could be attributed to the fact that there was an increased secretion of reproductive hormones during pregnancy which favors the proliferation of *C. albicans* (Sobel 1997). High levels of estrogen provide an increased amount of glycogen in the vagina. In this study, pregnant women in their third trimester had the highest prevalence of 57(47%). This result supports previous findings that pregnant women within their 3rd trimesters had the highest prevalence of 30.40% and 32.41% respectively for *T. vaginalis* and *Candida albicans* as reported by (Okonkwo et al., 2010; Okpara et al., 2009). The result of this study however
differed with that of Oviasogie 2009, who reported that women in their second trimester had the highest occurrence of Candida infection of (68.8%). During pregnancy, the vagina is more sensitive, and the infection occur significantly more often. This is especially true in the last trimester of pregnancy, due to the increased amount of glycogen in the vagina and high levels of hormones. The result on the occurrence of Candida albicans in different age groups suggests that some age groups are more prone to the infection than others. The results showed that ages 20-29 years had the highest prevalence of vaginal candidiasis of 38.5%. This differed with the results of Adad et al. (2001), who reported that Candida species were most frequent among younger patients, especially those ages under 20 years. These results showed that the prevalence rate among antibiotics users was 76(33.6%) which was higher than non antibiotic users 61(35.5%). The result of this present study disagrees with that of Nwadioha et al (2010), who reported that broad spectrum antibiotic users posed a 16% risk for vaginal candidiasis. The use of antibiotics is a predisposing factor to colonization of Candida and equally the absence of risk factors do not necessarily guard against vaginal candidiasis (Sobel et al 1998).The prevalence according to the mode of dressing among the women showed an increase in Candida albicans in women who put on tights and synthetic underwears 90(40%) against those who do not. These materials are being noted to trap bacteria and increase temperature in the vagina areas thereby creating a warm, moist environment, a pre-requisite for the development and proliferation of the pathogenic strains of Candida albicans.

5. CONCLUSION
A relatively high prevalence of Candida albicans was observed in this study. This was similar to that found in other parts of Nigeria. This study has shown that factors such as age of the women, use of antibiotics, stage of pregnancy and dressing among women were responsible for high prevalence of Candida albicans. These findings should be taken into account in further studies concerning presence of C. albicans among women in Nigeria since it is responsible for female genital discharge. More studies should be encouraged in this direction to reduce the incidence of female genital discharge. There should also be regular public enlightenment for young women on the importance of personal hygiene, appropriate use of antibiotics and proper choice of cloths to avoid wearing tight fitting underpants that allow the proliferation of pathogenic organisms like C. albicans. Females are equally advised to go for regular routine check-up.
