### ABSTRACT

A study was conducted to determine the phenotypic relationship between linear body measurements, Heart girth (HG), Body depth (BD), Rump height (RH), Height at wither (HAW), Body length (BL) and body weight (BWT); and to predict body weight from linear body measurements using two hundred and ninety four West African Dwarf (WAD) goats (250 females and 44 males) in four age groups varied between 6-12 months (OPPI-without pair of permanent incisors), 1-1.5 year (1PPI), 1.5-2 year (2PPI), and 2.5 – 3 years (3PPI). The data obtained from this study were analyzed using linear and multiple regressions. Results showed that the mean live body weight of female WAD goats in the four age category were  $9.563 \pm 4.844$ ,  $12.628 \pm 4.958$ ,  $21.077 \pm 6.558$  and  $23.885 \pm 3.652$  kg, respectively while males of age group (OPPI) and (PP1) recorded  $6.963 \pm 1.43$  and  $12.235 \pm 4.815$ kg respectfully. There were significant correlation ( $P < 0.001$ ) between body weight and measured linear measurements, HG ( $r = 0.681$ ), BD ( $r = 0.669$ ), RH ( $r = 0.607$ ), HAW( $r = 0.571$ ), BL ( $r = 0.634$ ), in the pooled group irrespective of sex or age. Simple linear regression analysis showed that body weights could be predicted accurately from heart girth at different ages studied; multiple regression showed high accuracy when more variables were included in the prediction equations ( $R^2 = 0.803$ ,  $0.694$  and  $0.710$  for male, female and male/female groups respectively in the pooled age group). This indicated that there was high correlation between linear body measurements and live body weight which could be used as selection criteria in improving meat production in WAD goat. The highest  $R^2$  was obtained when all the body measurements were included in the regression equations; this suggests that live body weight could be estimated more accurately by combination of two or more linear measurements.

**Key words:** WAD goat, body weight, linear body measurements, relationship

### Introduction

The main purposes of animal breeding practices are to improve traits of economics values; body weight being an important economic trait in the selection of animals demands an accurate estimation to enhance livestock breeding and production. Furthermore, knowledge of animal live weight is an important tool for farmers in making decisions, such as estimation of market prices for live animals, determining correct dosages in drug administration, determining animal's feed requirements for growth, maintenance, and production (Mahieu *et al.*, 2011; Tsegaye *et al.*, 2013; Chitra *et al.*, 2012). The conventional method of estimating live weight is the use of weighing balance (Shirzeyli *et al.*, 2013). However, in the rural communities under field condition where the goats are kept for commercial purposes, these scales are not in use partly due to cost, labour and technicality involved in the use of weighing scales. This has led to difficulty in live animal marketing in relation to price setting. Nevertheless, there is need to estimate live weight of animals especially goats from simple and easily measurable morphological traits such as linear body measurements (Olatunji-akioye and adeyemo, 2009). Pesmen and Yardimci, (2008) indicated that different models might be needed to predict body weight in different environmental conditions, breed, age and gender. The use of linear body measurements in estimating live weight in goats have been reported by several authors (Fajemilehin and Salako, 2008; Adeyinka and Mohammed, 2006; Nsoso *et al.*, 2004; Islam *et al.*, 1991). Most of these reports are however limited to research institutes without major effect on the goat based population. Therefore, the aim of this study was to establish regression equation models that could be potentially used to predict body weight in West African dwarf goats under field conditions.

### Materials and Methods

#### Study Location

The study was carried out in Obio Akpa community in Oruk Anam LGA of Akwa Ibom State, South-South Nigeria. Obio Akpa is located between latitudes  $5^{\circ}17'N$  and  $5^{\circ}27'N$  and between longitudes  $7^{\circ}27'E$  and  $7^{\circ}58'E$  with an annual rainfall ranging from 3500mm – 5000mm and average monthly temperature of  $25^{\circ}C$ , and relative humidity between 60-90%. It is in the tropical rainforest zone of Nigeria. The people in the study areas depend on livestock and crop production, (Wikipedia, 2016).

### **Data collection methods**

A total of two hundred and ninety four (294) WAD Goats comprising two hundred and fifty (250) females and forty-four (44) males in four (4) age groups as 0PPI, 1PPI, 2PPI and 3PPI; which was equivalent to 6-12 months, 1-1.5 year, 1.5-2 year and 2.5 – 3 years, respectively were examined for their body weight and linear body measurements, The age was estimated based on the pair of permanent incisor (PPI) as describe by Devendra and Mcleroy (1982). Linear body measurements studied included, heart girth (HG), Body depth (BD), Rump height (RH), Height at wither (HAW) and Body length (BL). All measurements were done early in the morning before the animals were released for grazing. All animals were under semi-intensive system of management. The animals were measured in their standing position under field conditions using flexible tape in centimeters, as previously described for goats (Hassan and Ciroma, 1991 and Khan *et al.*, 2006). Body weight was measured using a measuring scale in kg, Heart girth (circumference of the chest), Body Depth (circumference of the region immediately after the hind leg towards the abdomen), Rump height (distance from the ground to the rump), Height at Withers (distance from the ground to the withers) and Body Length (distance from the occipital protuberance to the base of the tail), all in centimeters.

**Statistical Analysis:** The data obtained were analyzed using the Statistical Package for the Social Sciences (SPSS) version 20.0. Correlations (Pearson's correlation coefficients) between body weight and different body measurements were computed within each sex and age group. Regression analysis was employed to predict live weight from body measurements. The choice of the best fitted regression model was selected using coefficient of determination ( $R^2$ ) and Mean standard error (MSE). The multiple regression models were followed to estimate body weight from body measurements for male and females in separate analyses. The full regression model of the measurements (all the five linear body measurements) was defined as:

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \beta_4 X_4 + \beta_5 X_5$$

Where, Y = dependent variable (body weight),  $\beta_0$  = intercept,  $\beta$ 's = regression coefficients, X's = independent variables (HG, BD, RH, HAW and BL).

## **RESULTS AND DISCUSSION**

### **BODY WEIGHT AND LINEAR BODY MEASUREMENT IN WEST AFRICAN DWARF GOATS**

Table 1 indicates the live body weight and linear body measurement for WAD goats. The mean body weight of female West African Dwarf goats in the four age categories (OPP1 1PP1, 2PP1 and 3PP1) were noted as  $9.563 \pm 4.844$ ,  $12.628 \pm 4.958$ ,  $21.077 \pm 6.558$  and  $23.885 \pm 3.652$ kg respectively, while the male of the first and second age groups (OPPI and 1PPI) recorded  $6.963 \pm 1.143$  and  $12.235 \pm 4.815$  respectively. With regard to the linear body measurements of West African dwarf goats, the results showed that the female mean heart girth ( $18.029 \pm 4.174$ ,  $21.840 \pm 1.756$ ,  $25.070 \pm 2.594$  and  $26.048 \pm 2.227$ cm), body depth ( $19.940 \pm 5.630$ ,  $24.977 \pm 2.276$ ,  $29.148 \pm 3.593$  and  $30.834 \pm 2.939$ cm); rump height ( $15.665 \pm 3.201$ ,  $18.208 \pm 1.790$ ,  $20.136 \pm 1.894$  and  $20.271 \pm 2.122$  cm); height at wither ( $14.121 \pm 2.720$ ,  $16.775 \pm 1.751$ ,  $18.144 \pm 1.768$  and  $18.065 \pm 1.372$  cm) and body length ( $18.132 \pm 4.540$ ,  $23.048 \pm 2.004$ ,  $25.191 \pm 2.404$  and  $26.362 \pm 2.062$  cm) in the respective age groups. Both the live weight and linear body measurements increased as age increases, indicating that the studied population were in good health conditions. Dereje and Aynalem, (2013) earlier stated that live body weight of goat increase as age increases till the first set of incisors and gradually the rate of increase reduces to maturity. Adeyinka and Mohammed (2006) reported lower mean body weight in female goats than males, which is at variance with the present study. This may be as a result of differences in breeds used. It was very difficult to get male goats older than one year under field condition, this was because few male goats are usually used for breeding purposes, and the rest are sold out when beyond one year of age. This makes it difficult to present the body measurements of male goat in all the age groups except the first and second age groups (OPPI and 1PPI).

Bwt =Body weight, RH=Rump Height, BD=Body Depth, HAW=Height at wither, HG=Heart Girth, BL=Body Length, M=Male, F=female, M/F=male and female, PP1=pair of permanent incisors

Pooled = combination of data irrespective of age

Table 2 shows the relationship between Body weight and linear body measurement in West African dwarf goats. The highest coefficient of correlation was obtained between BWT and HG in males ( $r = 0.748$ ) when all ages were considered. This implies that better prediction of body weight could be obtained in male WAD goats than in females. This result is in line with the findings of Alemayehu and Tikabo (2010) who obtained a higher correlation between body weight and linear body measurements in male highland sheep than the females. In 0PP1 male group, there were very high and significant correlations between body weight and all linear body measurements studied. This suggests that selection of animals at this age group will lead to higher live body weight.

### Prediction of Body weight from Linear Body Measurement

The prediction equations to estimate body weight from linear measurements using regression analysis for females at different age groups is shown in Table 3. The results shows that in OPPI, the equation with heart Girth alone was statistically significant ( $p < 0.001$  with  $R^2$  value of 0.44 and MSE value of 19.195, which indicates that 44.4% of the variance in BWT was explained by the model. The  $R^2$  values increased as the no of variables increased while the MSE values decreased with increased no of variables. When 1PPI age group was considered the same trend was observed.

In 2PPI age group, the regression analysis of how well HG predicts BWT was statistically significant with  $R^2$  and MSE values of 0.618 and 26.877 respectively, indicating that 61.8% of the variance in BWT was explained by the model. As more variable were included the  $R^2$  values also increased, when all the five variables were included in the equation, the  $R^2$  and MSE values were 0.708 and 22.759 respectively indicating that 70.8% of the variance in BWT was explained by the model. The same trend was also observed in 3PPI age group.

The result of linear body measurement as related to body weight in male West African dwarf goats is shown in Table 4. The results indicates that in the two age groups (0PPI and 1PPI), in which male animals were available for measurement, the regression analysis of how well linear body measurements predict BWT were statistically significant ( $p < 0.001$ ), with the highest  $R^2$  value and least MSE obtained when all the five variables were included in the equation.

The prediction of body weight from interaction of age and sex as related to linear body measurements presented in Table 5 indicates that predictions were more accurate for males than females. This could be due to varying deposition of fat in the two sexes as earlier reported by Bassono *et al.*,(2001). Generally, it was observed that the higher the variables, the higher the coefficient of determination (R<sup>2</sup>) and better prediction of body weight based on linear body measurements. This agrees with Topal *et al.*, (2003) who reported that either R<sup>2</sup> or MSE may be confidently applied to investigate the fitting state of simple and multiple regression models to actual data for estimation of body weight in livestock.

In all the age and sex groups, there was high correlation between BWT and HG even as the highest variation of body weight was accounted for by the combination of all the five variables (HG, BD, RH, HAW, & BL). This observation is in agreement with the work of Topal and Macit (2004), Tadesse and Gebremariam (2010), and Raja *et al.*, (2013). Moreover, the highest R<sup>2</sup> obtained in the pooled age groups when all the body measurements were included in the regression equations suggest that body weight could be estimated more accurately by combination of two or more variables than HG alone. More so, the coefficient of determination R<sup>2</sup> was highest in the equations with pooled data (irrespective of age) compared to equations formed at different age groups (Table 5). Hence, the above equations may be used to predict the body weight of West African dwarf goats at different age groups.

Table 6: Comparison of measured and calculated live weight values for West African dwarf Goat

| Age    | Sex | M-BWT(kg) | Corresponding results based on regression equations for live weights (kg) |        |          |              |                 |
|--------|-----|-----------|---|--------|----------|--------------|-----------------|

M-BWT = Measured Body weight, RH=Rump Height, BD=Body Depth, HAW=Height at wither, HG=Heart Girth, BL=Body Length, M=Male, F=female, M&F=male and female, PP1=pair of permanent incisors, Pooled = combination of data irrespective of age

The comparison of the actual body weight and predicted body weight from linear regression equations are demonstrated in Table 6. The actual and computed body weights were more or less similar which confirms the

fact that body weight can be predicted from linear body measurements with accuracy. The present study is in agreement with Tsegay *et al.*, (2013), Slippers *et al.*, (2000) and Myeni and Slippers 1997. The same authors indicated that there were no significant differences between actual body weight and body weight predicted with equations.

## CONCLUSION

The body weight and linear body measurements were significantly correlated with each other. Body weight had higher correlation with HG than other body measurements (BD, RH, HAW and BL). In all investigated sex and age group, the highest  $R^2$  was obtained when all the body measurements were included in the regression equations; this suggests that body weight could be estimated with more precision by combination of two or more linear body measurements.

Body weight can be predicted from body measurements with high accuracy to support improvement and husbandry practices of West Africa dwarf goats.
