ABSTRACT;
Background; Ovarian masses are very common in pre- and postmenopausal women and are usually an incidental finding. The treatment of an ovarian cyst relies on its nature, and accurate preoperative discrimination of benign and malignant cysts is therefore of crucial importance. This study was done to ascertain malignancy in adolescent women having ovarian masses. Objective; To determine the frequency of malignancy in adolescents and young women presenting with ovarian masses. Material and Methods; Patients (n = 98) fulfilling inclusion criteria from outpatient department of Nishtar Hospital, Multan, Pakistan were included in the study. Informed consent was taken from each patient ensuring confidentiality and the fact that there was no risk to the patient while taking part in this study other than the disease itself. Detailed history and physical examination of our study cases were arranged by the researcher itself. Data were entered and analyzed by SPSS. Results; Mean age of our study cases was 24.27 ± 5.19 years (with minimum age of our study cases was 15 years while maximum age was 34 years). Our study results have indicated that majority of our study cases i.e. 59 (60.2 %) were aged equal/less than 25 years. Of these 98 study cases, 43 (43.9 %) belonged to rural areas and 55 (56.1%) belonged to urban areas. Monthly family income up to Rs. 35000 was noted in 58 (59.2%) and more than Rs. 35000 was noted in 40 (40.8%) of our study cases. Of these 98 study cases, 66 (67.3%) were illiterate and 32 (32.7%) were literate. Family history of family cancer was noted in 19 (19.4%) of our study cases. Mean disease duration was 14.78 ± 5.13 months. Mean body mass index of our study cases was 26.02 ± 2.13 kg/m² and obesity was present in 23 (23.5 %) of our study cases. Of these 98 study cases, 27 (27.6 %) were having history of use of oral contraceptives. Malignancy was diagnosed in 23 (23.5 %) of our study cases. Conclusion; There was high frequency of malignancy noted among women having ovarian masses in our study cases. Ovarian masses were significantly associated with residential status and family history. Gynecologists treating such patients should monitor such suspected cases for early diagnosis which will improve treatment rate and quality of life of our patients.

Keywords; Ovarian Masses, Malignancy, Frequency, adolescents.

INTRODUCTION;
Ovarian cancer is the second most common gynecological malignancy in women with cancer. It is the 8th most common cancer among women, fifth leading cause of cancer related death among women, and is the deadliest of the gynecologic cancers. The age standardized incidence rates (ASR) of ovarian cancer in Karachi Pakistan, is 10.2 per 100000 per year. In contrast ASR in India ranged from 0.9 (Silchar town) to 8.4 per 100000 per year. Ovarian cancer accounted for 204000 new cases and 125000 deaths worldwide. It is one of the most aggressive gynecological malignancies having a high mortality rate owing to its advance stage on diagnosis. The mortality rate has not decreased because of its vague symptoms and late diagnosis. Patients with a malignancy should undergo an appropriate staging procedure or debulking surgery carried out in specialized...
surgical centers. This is associated with a better median survival. Ovarian tumors can be benign or malignant. Most ovarian tumors are benign. Approximately 3% are malignant. Various studies have addressed the likelihood of malignancy within ovarian mass. The likelihood ranges from 0.38% to 18.67% and is population dependent. Approximately 10% women undergo surgery for an ovarian mass in their lifetime. Ovarian cancer in children and young adults are rare and their type also differs from those diagnosed in old women. Majority of ovarian tumors occurring in girls between ages of birth and 19 yrs are of non-epithelial origin, similar to other malignancies diagnosed in this age group. Ovarian pathology, although rare, must be included in the differential diagnosis of all girls who present with abdominal pain, mass or precocious puberty. It is important for gynecologists to have a high suspicion if a young woman comes with adnexal masses and a low threshold for surgery is required. According to a study conducted on ovarian masses in children less than 18 years old, Germ cell tumors are the most common malignancy, epithelial cell tumors are less likely. Epithelial cysts and teratomas are the most common benign lesions.

Among Asian countries, Pakistan not only has the highest rate of breast cancer but also of ovarian cancer. According to a study in Karachi, Ovarian cancer is the third most common malignancy in women. In Pakistan, the incidence of ovarian cancer involves a relatively younger age group with a strong family history in every 4th case. A study in china showed 13.6% malignancy in ovarian masses in adolescents.

**MATERIAL AND METHODS;**

A total of young girls and women age 12 to 35 years with adnexal masses of ovarian origin with disease duration of 6 months or more. Ovarian masses were defined as Presence of any one of five categories according to the presence of septa and a solid component as follows to define ovarian masses:

- Unilocular cyst: a cyst without septa and a solid component
- Unilocular solid cyst: a unilocular cyst with a solid component
- Multilocular cyst: a cyst with at least one septum but no solid component
- Multilocular solid cyst: a multilocular cyst with a solid component
- Solid tumor: a tumor where the solid components comprise 80% or more of the tumor when assessed in two-dimensional section

Masses other than ovarian origin, pregnant patients, ovarian masses with other malignancies, ovarian masses which have already metastasized were excluded from our study.

Patients (n = 98) fulfilling inclusion criteria from outpatient department of Nishtar Hospital, Multan, Pakistan were included in the study. Informed consent was taken from each patient ensuring confidentiality and the fact that there was no risk to the patient while taking part in this study other than the disease itself. Detailed history and physical examination of our study cases were arranged by the researcher itself. These study underwent baseline investigations like blood tests (done by a pathologist having more than 5 years experience after post graduation), ultrasonography (done by a consultant Sonologist having more than 5 years experience after post graduation) and Biopsy (done by a pathologist having more than 5 years experience after post graduation) to diagnose status of ovarian masses (malignant). Data was analyzed with statistical analysis program (SPSS). The quantitative variables like age, BMI and duration of disease was presented as mean and standard deviation. Frequencies and percentages were calculated for age groups, pattern of ovarian masses (malignant), family history, use of oral contraceptive drugs, residential status and educational status.

**RESULTS;**

Our study comprised of a total of 98 patients meeting inclusion criteria of our study. Mean age of our study cases was 24.27 ± 5.19 years (with minimum age of our study cases was 15 years while maximum age was 34 years). Our study results have indicated that majority of our study cases i.e. 59 (60.2 %) were aged equal/less than 25 years. Of these 98 study cases, 43 (43.9 %) belonged to rural areas and 55 (56.1%) belonged to urban areas. Monthly family income up to Rs. 35000 was noted in 58 (59.2%) and more than Rs. 35000 was noted in 40 (40.8%) of our study cases. Of these 98 study cases, 66 (67.3%) were illiterate and 32 (32.7%) were literate. Family history of family cancer was noted in 19 (19.4%) of our study cases. Mean disease duration was 14.78 ± 5.13 months. Mean body mass index of our study cases was 26.02 ± 2.13 kg/m² and obesity was present in 23 (23.5 %) of our study cases. Of these 98 study cases, 27 (27.6 %) were having history of use of oral contraceptives. Malignancy was diagnosed in 23 (23.5 %) of our study cases.

DISCUSSION;

Ovarian masses are very common and 10% of women have an operation during their life for investigation of an ovarian mass. These masses are typically found in asymptomatic women who have imaging for another reason, or for investigation of non-specific abdominal or pelvic pain. In premenopausal women, these cysts are typically benign; however, it is important to determine if further investigation is required. The overall incidence of a symptomatic ovarian cyst in a premenopausal female being malignant is approximately 1 in 1000, increasing to 3 in 1000 at the age of 50 years \(^{14,15}\).

Our study comprised of a total of 98 patients meeting inclusion criteria of our study. Mean age of our study cases was 24.27 ± 5.19 years (with minimum age of our study cases was 15 years while maximum age was 34 years). Our study results have indicated that majority of our study cases i.e. 59 (60.2 %) were aged equal/less than 25 years. A study conducted by Tangjitgamol et al \(^{16}\) from Thailand has reported 21 years mean age which is close to our study results. A study conducted by Gupta et al \(^{17}\) has reported similar results.

Of these 98 study cases, 43 (43.9 %) belonged to rural areas and 55 (56.1%) belonged to urban areas. Monthly family income up to Rs. 35000 was noted in 58 (59.2%) and more than Rs. 35000 was noted in 40 (40.8%) of our study cases. Of these 98 study cases, 66 (67.3%) were illiterate and 32 (32.7%) were literate. Family history of family cancer was noted in 19 (19.4%) of our study cases. Mean disease duration was 14.78 ± 5.13 months. Mean body mass index of our study cases was 26.02 ± 2.13 kg/m\(^2\) and obesity was present in 23 (23.5 %) of our study cases. Saluja et al from India \(^{18}\) reported similar findings which are consistent to our study results. Of these 98 study cases, 27 (27.6 %) were having history of use of oral contraceptives. Malignancy was diagnosed in 23 (23.5 %) of our study cases. A study conducted by Ashraf et al \(^{19}\) has reported 35 % malignant masses which is close to our study results. Saluja et al from India \(^{18}\) reported benign masses on clinical assessment to be 75 and malignancy in 25 % while on ultrasound 70 % benign and 30 % were malignant. These findings of Saluja et al \(^{18}\) are close to our study results. Another study conducted by Parmer et al \(^{20}\) also reported 25.33 % malignancy which is in compliance with our study results.
CONCLUSION;
There was high frequency of malignancy noted among women having ovarian masses in our study cases. Ovarian masses were significantly associated with residential status and family history. Gynecologists treating such patients should monitor such suspected cases for early diagnosis which will improve treatment rate and quality of life of our patients.
