Abstract

This paper developed an alternative statistical method for the analysis of time or space ordered data. The proposed method used the ranks of successive differences between the observations adjust for the order, direction and magnitudes of the successive differences. Chi-squared test statistic based on the ranks of the successively ordered data is developed to test for the possible existence of any statistical differences between the scores by subjects in the time or space ordered population. Some sample data were used to illustrate the proposed method. The result of the analysis shows that the present method is as powerful as some of the existing non-parametric methods that can be used for the same purpose at least for the present data but preferably for use if the available data set is ordered in time or space.

Keywords: Sign test, ordered samples, ranks, time, and space.

1. Introduction

Sometimes a researcher may be interested in analyzing some data obtained from subjects at several points in time. These may include responses to diagnostic tests administered at several time periods; students' examination results during their years of study; candidates' scores at repeated job interviews; scores by soccer teams or competitors recorded for several seasons; etc. These types of data represent repeated measures or observations on each subject studied.

If a random sample of these repeated measures drawn from a number of related populations that do not satisfy the necessary assumptions for the use of parametric tests, then use of non-parametric method is indicated and preferable. Non parametric methods that readily suggest themselves for this purpose include the Cochran Q test which requires the observations to be dichotomous assuming only two possible values (Gibbons 1971, Gibbons 1993), Siegel, 1956; Hollander and Wolfe, 1999, Freidlin and Gastwirth 2000). the Extended Median Test for matched samples which analysis independent samples when the parametric t-test cannot used (Oyeka et al. 2010) and Ties Adjusted Extended Sign Test for Ordered Data which analyses ordered repeated measures that are related in time, space or condition, (Oyeka et al. 2012), etc. In this paper, we propose an alternative statistical method for the analysis of time ordered repeated measures. The proposed method is based on the extension of the sign test using the ranks of successive differences between the observations.

2. The Proposed Method

Let $(x_{i1}, x_{i2}, x_{i3}, \dots, x_{ik})$ be the i th batch or block of observations or scores in a random sample of size "n" drawn from "k" related or time ordered populations X_1, X_2, \dots, X_k for $i= 1, 2, \dots, n$ where k may be indexed in time. Populations, X_2, \dots, X_k may be measurements on as low as the ordinal scale.

To develop an extended sign test by ranks for the purpose, we let

$$d_{ij} = x_{ij} - x_{ij+1} \quad 1$$

for $i = 1, 2, \dots, n; j = 1, 2, \dots, k-1$

That is we take the differences between observations or scores on successive treatment levels or time period for each subject. Let

$$u_{ij} = \begin{cases} 1, & \text{if } d_{ij} > 0 \\ 0, & \text{if } d_{ij} = 0 \\ -1, & \text{if } d_{ij} < 0 \end{cases} \quad 2$$

Thus u_{ij} assume the value 1, if d_{ij} the difference between the scores earned at the j th and $(j+1)$ th treatment levels, by the subject in the i th block is positive; the value 0 if it is zero; and the value -1, if it is negative; if $i = 1, 2, \dots, n; j = 1, 2, \dots, k$

Let

$$\pi_j^+ = P(u_{ij} = 1); \pi_j^0 = P(u_{ij} = 0); \pi_j^- = P(u_{ij} = -1) \quad 3$$

where

$$\pi_j^+ + \pi_j^0 + \pi_j^- = 1 \quad 4$$

To develop the extended sign test based on ranks, we now instead of using the difference d'_{ij} s directly themselves, we first ranks the absolute values of these differences within each batch or block either from the smallest to the largest or largest to the smallest. Tied absolute differences within each block are as usual assigned their mean ranks.

Thus let r_{ij} be the rank assigned to the absolute value of d_{ij} , the difference between observations from populations X_j and X_{j+1} , in the i th block for $i=1,2, \dots, n$; $j=1,2, \dots, k-1$.

Define

$$W_j = \sum_{i=1}^n r_{ij} u_{ij} \quad 5$$

for $j=1,2, \dots, k-1$

Also let

$$W = \sum_{j=1}^{k-1} W_j = \sum_{i=1}^n r_{ij} u_{ij} \quad 6$$

W_j is the difference between the total or sum of the ranks assigned to absolute differences with positive signs and sum of the ranks assigned to absolute differences with negative signs between the scores by all subjects at treatment levels X_j and X_{j+1} for $j=1,2, \dots, k-1$. That is W_j measures the difference between the sum of the ranks assigned to positive differences and the sum of the ranks assigned to negative differences between observations from successive treatment levels or populations for all subjects. Note, W_j is independent of zero differences. W is a measure of the overall total rank sum differences for all subjects and treatment levels. Interest is to use W as a test statistic for the null hypothesis of no difference between subjects in their response to the treatment levels.

Now

$$E(u_{ij}) = \pi_j^+ - \pi_j^-; \text{Var}(u_{ij}) = \pi_j^+ + \pi_j^- - (\pi_j^+ - \pi_j^-)^2 \quad 7$$

The expected value of W_j is from Equation 5

$$E(W_j) = \sum_{i=1}^n r_{ij} E(u_{ij}) = (\pi_j^+ - \pi_j^-) \sum_{i=1}^n r_{ij}$$

or

$$E(W_j) = (\pi_j^+ - \pi_j^-) R_j \quad 8$$

where

$R_j = \sum_{i=1}^n r_{ij}$ is the sum of the ranks assigned to all the 'n' absolute differences between the observations drawn from populations X_j and X_{j+1} , $j=1,2, \dots, k-1$.

Note that π_j^+ ; π_j^0 and π_j^- are respectively the probabilities that observations from population X_j are on the average greater than, equal to or less than observations from population X_{j+1} .

In other words, π_j^+ ; π_j^0 and π_j^- provide a measure of the proportion of cases in which subjects scores are on the average rated or ranked higher (lower), the same as, or lower (higher) in treatment level or population X_j than in treatment level X_{j+1} . The sample estimates of these probabilities are

$$\hat{\pi}_j^+ = \frac{f_j^+}{n}; \hat{\pi}_j^0 = \frac{f_j^0}{n}; \hat{\pi}_j^- = \frac{f_j^-}{n} \quad 9$$

where f_j^+ , f_j^0 and f_j^- are respectively the number of 1s, 0s and -1s in the frequency distribution of these numbers in u_{ij} , for $i=1,2, \dots, n$ and each $j=1,2, \dots, k-1$. Note that f_j^+ , f_j^0 and f_j^- are respectively the number sampled subjects who are rated or ranked higher(lower), the same as, or lower(higher) at response or treatment level X_j than at level X_{j+1} .

The variance of w_j is obtained by using equation 7 in equation 5 giving

$$\text{Var}(w_j) = \sum_{i=1}^n r_{ij}^2 \text{Var}(u_{ij}) = (\pi_j^+ + \pi_j^- - (\pi_j^+ - \pi_j^-)^2) \sum_{i=1}^n r_{ij}^2 \quad 10$$

Note that $\pi_j^+ - \pi_j^-$ is the difference between the probabilities. That observation from population X_j are on the average greater than observations from population X_{j+1} and the probability that observations from population X_j are on the average less than observations from population X_{j+1} . That is $\pi_j^+ - \pi_j^-$ provides a measure of the difference between the proportion of all subjects who on the average are rated or ranked higher at treatment level X_j than at treatment level X_{j+1} and the proportion of all subjects who are rated or ranked lower at treatment level X_j than at treatment level X_{j+1} . This difference is estimated from the expression

$$W_j = (\pi_j^+ - \pi_j^-) R_j = \widehat{W}_j^+ - \widehat{W}_j^- \quad 11$$

where \widehat{W}_j^+ and \widehat{W}_j^- are respectively the sum of the ranks of absolute differences with positive and negative signs of the differences between the scores of all subjects of treatment levels X_j and X_{j+1} for $j=1,2, \dots, k-1$.

It can easily be seen from equations 8 and 11 that W_j provide a measure of the amount by which the proportion of the total or sum of the ranks assigned to positive absolute differences between the scores of subjects at treatment levels X_j and X_{j+1} is on the average greater (lower) than the proportion of the total ranks assigned to negative absolute differences.

If populations X_j and X_{j+1} have equal medians, we would expect that $\pi_j^+ - \pi_j^-$ would be equal to zero for $j=1, 2, \dots, k-1$. In other words, a null hypothesis that would be of interest in this case is

$$H_0: \pi_j^+ - \pi_j^- = 0 \text{ versus } H_1: \pi_j^+ - \pi_j^- \neq 0, \text{ say} \quad 12$$

for $j=1, 2, \dots, k-1$.

Under this null hypothesis, the test statistic $\chi_j^2 = \frac{W_j^2}{\text{var}(W_j)}$ 13

for $j = 1, 2, \dots, k-1$.

has approximately the Chi Square Distribution with degrees of freedom for significantly large 'n' and may be used to test the null hypothesis of equation 12 where W_j and $\text{Var}(W_j)$ are given in equations 11 and 10 respectively. H_0 is rejected at the α level of significant if

$$\chi_j^2 \geq \chi_{1-\alpha,1}^2 \quad 14$$

Otherwise H_0 is accepted.

However, to avoid committing a type II error too frequently, it is recommended that the calculated Chi-Square value of Equation 14 be compared with the tabulated Chi-Square value with k-1 degree of freedom instead of 1 degree of freedom.

However, a null hypothesis that is of greater interest here in the case of repeated measures is that k related populations have equal medians. To develop the required test statistic, we note from equation 6 that

$E(W) = \sum_{j=1}^{k-1} E(W_j)$ which using equation 8 yields

$$E(W) = \sum_{j=1}^{k-1} (\pi_j^+ - \pi_j^-) \sum_{i=1}^n r_{ij} = \sum_{j=1}^{k-1} (\pi_j^+ - \pi_j^-) R_{.j} \quad 15$$

Also from equation 10, we have

$$\text{Var}(W) = \sum_{j=1}^{k-1} \text{Var}(W_j) = \sum_{j=1}^{k-1} (\pi_j^+ + \pi_j^- - (\pi_j^+ - \pi_j^-)^2) \sum_{i=1}^n r_{ij}^2 \quad 16$$

Now it can be seen from Equation 15 that the sample estimate of $\sum_{j=1}^{k-1} (\pi_j^+ - \pi_j^-) R_{.j}$ is given by the expression

$$W = \sum_{j=1}^{k-1} (\pi_j^+ - \pi_j^-) R_{.j} = W^+ - W^- \quad 17$$

where W^+ and W^- are respectively the sums of the ranks of absolute differences with positive and negative signs of the differences between the scores of all subjects for all treatment levels.

Also note that $\sum_{j=1}^{k-1} (\pi_j^+ - \pi_j^-) R_{.j}$ is a measure of how much on the average the proportion of the overall rank sums assigned to absolute differences with positive sign is greater (smaller) than the proportion of the overall rank sum of absolute differences with negative sign for all subjects and all sampled treatment levels.

Now if the k sampled populations have equal medians, that is if the differences between observations or scores in successive treatment levels are as likely to be positive or negative for all treatment levels, then the difference between π_j^+ and π_j^- would be expected to be zero for all $j=1, 2, \dots, k-1$. In other words testing whether k related and here time ordered populations have equal medians is equivalent to testing the null hypothesis.

$$H_0: \pi_1^+ - \pi_1^- = \pi_2^+ - \pi_2^- = \dots = \pi_k^+ - \pi_k^- = \pi^+ - \pi^- = 0 \text{ versus } H_1: \text{not all } \pi_j^+ - \pi_j^- = 0 \quad 18$$

for some $j = 1, 2, \dots, k-1$

where π^+, π^- and π^0 are respectively the common values of π_j^+, π_j^0 and π_j^- if H_0 is true for

$j = 1, 2, \dots, k-1$.

The sample estimates of these common probabilities or proportions under the null hypothesis of equation 18 are respectively

$$\begin{aligned} \hat{\pi}^+ &= \sum_{j=1}^{k-1} \frac{\hat{\pi}_j^+}{k-1} = \sum_{j=1}^{k-1} \frac{f_j^+}{n(k-1)}, \\ \hat{\pi}^0 &= \sum_{j=1}^{k-1} \frac{\hat{\pi}_j^0}{k-1} = \sum_{j=1}^{k-1} \frac{f_j^0}{n(k-1)}, \\ \hat{\pi}^- &= \sum_{j=1}^{k-1} \frac{\hat{\pi}_j^-}{k-1} = \sum_{j=1}^{k-1} \frac{f_j^-}{n(k-1)} \end{aligned} \quad 19$$

In this case, that is under H_0 , the sample estimate of W (equation 16) may be obtained from equation 17 as

$$W = (\pi_j^+ - \pi_j^-) \sum_{j=1}^{k-1} R_{.j} = (\pi_j^+ - \pi_j^-) R_{..} = W^+ - W^- \quad 20$$

where

$$R_{..} = \sum_{j=1}^{k-1} R_{.j} = \frac{nk(k-1)}{2} \quad 21$$

and W^+ and W^- are again respectively the sums of the ranks of absolute differences between scores with positive sign and those with negative sign for all subjects and all treatment levels.

The corresponding sample estimates of the variance of W under H_0 is from equation 16

$$\text{Var}(W) = (\hat{\pi}^+ + \hat{\pi}^- - (\hat{\pi}^+ - \hat{\pi}^-)^2) \sum_{j=1}^{k-1} \sum_{i=1}^n r_{ij}^2 \quad 22$$

Note that if there are no tied observations in each of the 'n' blocks or batches of samples then the estimated variance of W (Equation 22) simplifies to

$$\text{Var}(W) = \frac{nk(k-1)(2k-1)}{6} (\hat{\pi}^+ + \hat{\pi}^- - (\hat{\pi}^+ - \hat{\pi}^-)^2) \quad 23$$

Since under the situation $\sum_{j=1}^{k-1} \sum_{i=1}^n r_{ij}^2 = \frac{nk(k-1)(2k-1)}{6}$

Now under the null hypothesis of equation 18, the test statistic

$$\chi^2 = \frac{w_j^2}{\text{Var}(W)} = \frac{w^2}{(\hat{\pi}^+ + \hat{\pi}^- - (\hat{\pi}^+ - \hat{\pi}^-)^2) \sum_{j=1}^{k-1} \sum_{i=1}^n r_{ij}^2} \quad 24$$

which under H_0 has approximately the Chi-Square Distribution with $k-1$ degree of freedom for significantly large 'n' and may be used to test H_0 where W is given in Equation 20, the variance of W is given in Equation 22 if there are many tied absolute differences or by Equation 23 if there are no ties or only very few ties in the data.

The null hypothesis is rejected at the α level of significant if

$$\chi^2 \geq \chi_{1-\alpha, k-1}^2 \quad 25$$

Otherwise, accepted. In this case, one would then proceed to test the null hypothesis of equation 12 to determine which pairs of successive populations or treatment levels have different medians that may have led to the rejection of the more general hypothesis of equation 18.

3. Illustrative Example

Shown in Table 1 is the data on the grade point averages (GPA) of a random sample of 17 students during each of the four years they spent studying for a degree in an academic program of a certain university shown also in the Table are the successive differences d_{ij} between three GPA's for each student by year.

Table 1: GPA's of a random sample of 17 students and their differences (Equation 1)

S/No of Students	GPA				Differences		
	Year1	Year2	Year3	Year4	d_{i1}	d_{i2}	d_{i3}
1	3.7	1.7	2.2	4.0	2.0	-0.5	-1.8
2	3.8	3.3	4.4	4.6	0.5	-1.1	-0.2
3	4.1	4.0	4.4	4.3	0.1	-0.4	0.1
4	4.2	3.1	2.5	3.8	1.1	0.6	-1.3
5	3.7	3.3	4.3	4.3	0.4	-1.0	0.0
6	3.7	2.9	4.1	3.6	0.8	-1.2	0.5
7	2.8	2.1	3.1	3.3	0.7	-1.0	-0.2
8	3.7	2.9	2.8	4.0	0.8	0.1	-1.2
9	4.1	2.7	4.0	3.9	1.4	-1.3	0.1
10	3.0	2.8	2.6	4.0	0.2	0.2	-1.4
11	3.5	2.5	3.7	3.7	1.0	-1.2	0.0
12	3.5	3.1	4.0	3.9	0.4	-0.9	0.1
13	4.5	4.4	4.6	4.7	0.1	-0.2	-0.1
14	4.0	3.4	4.3	4.2	0.6	-0.9	0.1
15	3.8	3.5	3.9	4.0	0.3	-0.4	-0.1
16	3.4	3.0	4.0	4.6	0.4	-0.1	-0.6
17	3.9	4.0	4.4	4.7	-0.1	-0.4	-0.3

To illustrate use of the proposed method with the above data, we apply Equation 1 to the differences d_{ij} in Table 1 to obtain the U_{ij} 's of Equation 2. We also rank the differences in each block from the smallest to the largest, assigning the smallest absolute difference rank 1 and the largest rank3. Tied absolute differences in each block are assigned their mean ranks. The results are shown in Table 2.

Table 2: ranks of absolute values of d_{ij} and values of u_{ij} (Equation 2) for the data of Table 1

S/No	r_{i1}	u_{i1}	$r_{i1} u_{i1}$	r_{i2}	u_{i2}	$r_{i2} u_{i2}$	r_{i3}	u_{i3}	$r_{i3} u_{i3}$	Total
1	3	1	3	1	-1	-1	2	-1	-2	
2	2	1	2	3	-1	-3	1	-1	-1	
3	1.5	1	1.5	3	-1	-3	1.5	1	1.5	
4	2	1	2	1	1	1	3	-1	-3	
5	2	1	2	3	-1	-3	1	0	0	
6	2	1	2	3	-1	-3	1	1	1	
7	2	1	2	3	-1	-3	1	-1	-1	
8	2	1	2	1	1	1	3	-1	-3	
9	3	1	3	2	-1	-2	1	1	1	
10	1.5	1	1.5	1.5	1	1.5	3	-1	-3	
11	2	1	2	3	-1	-3	1	0	0	
12	2	1	2	3	-1	-3	1	1	1	
13	1.5	1	1.5	3	-1	-3	1.5	-1	-1.5	
14	2	1	2	3	-1	-3	1	1	1	
15	2	1	2	3	-1	-3	1	-1	-1	
16	1	1	1	3	-1	-3	2	-1	-2	
17	1	-1	-1	3	-1	-3	2	-1	-2	
f_j^+		16			3			5		24(=f ⁺)
f_j^0		0			0			2		2(=f ⁰)
f_j^-		1			14			10		25(=f ⁻)
Total n.		17			17			17		51(n(k-1))
$\hat{\pi}_j^+$		0.941			0.176			0.294		0.471($\hat{\pi}^+$)
$\hat{\pi}_j^0$		0.00			0.00			0.118		0.039($\hat{\pi}^0$)
$\hat{\pi}_j^-$		0.059			0.824			0.588		0.490($\hat{\pi}^-$)
R_j	32.5			42.5			27.0			102.0(=R _{...})
W_j			30.5			-35.5			-14.0	-19.0(=W)

The values of $f_j^+, f_j^-, f_j^0, \hat{\pi}_j^+, \hat{\pi}_j^-, \hat{\pi}_j^0, R_j$ and W_j for $j = 1, 2, 3$ are calculated as discussed above and shown in Table 2.

Now from equation 17,

$$\begin{aligned} W &= (0.941 - 0.059)(32.5) + (0.176 - 0.824)(42.5) + (0.294 - 0.588)(27.0) \\ &= (0.882)(32.5) + (0.648)(42.5) + (0.294)(27.0) \\ &= 28.665 - 27.54 - 7.938 = 6.813 \end{aligned}$$

Also from equation 17, we have that

$$\begin{aligned} Var(W) &= (0.941 + 0.059 - (0.941 - 0.059)^2)(67.25) + (0.176 + 0.824 - (0.176 - 0.824)^2)(47.5) \\ &\quad + (0.294 + 0.588 - (0.294 - 0.588)^2)(52.5) = 14.930 + 689.5 + 41.79 = 124.87 \end{aligned}$$

Henceforth equation 19, we have that the test statistic for the equality of the four population medians is

$$\chi^2 = \frac{(-6.813)^2}{124.87} = 0.372 \text{ which with } 4-1 = 3 \text{ degrees of freedom is not statistically significant at } \alpha = 0.05 (\chi_{0.95;3}^2 = 7.815)$$

Now the common values π^+, π^0 and π^- are estimated from equation 19 using the frequencies in Table 2 as

$$\hat{\pi}^+ = \frac{24}{51} = 0.471; \hat{\pi}^0 = \frac{2}{51} = 0.039; \text{ and } \hat{\pi}^- = \frac{25}{51} = 0.490$$

Also from Table 2, we have that $W = W_1 + W_2 + W_3 = 30.5 - 35.5 - 14.0 = -19.0$

Since there are ties in the data, the variance of W is estimated from Equation 22 as

$$\begin{aligned} Var(W) &= (0.471 + 0.490 - (0.471 - 0.490)^2)(67.25 + 117.5 + 52.5) \\ &= (0.9606)(237.25) = 227.903 \end{aligned}$$

Hence to test the null hypothesis of Equation 18 that the four population medians are equal, we have from Equation 24 that

$$\chi^2 = \frac{(-19.0)^2}{227.902} = \frac{361}{227.902} = 1.584,$$

which with $4 - 1 = 3$ degrees of freedom is not statistically significant at $\alpha = 0.05 (\chi_{0.95;3}^2 = 7.815)$

Hence, we may conclude that the students did not experience differential academic performance during their four years of studies.

Note that the present test statistic is at least as powerful as the Wilcoxon Rank Sum Test. To show this, we note that relative efficiency of Wilcoxon (t_1) to the new method (t_2) is

4. Summary and conclusion

This paper developed an alternative statistical method for the analysis of time ordered repeated measures; from which an extension of the Sign Test using the ranks successive differences between the observations was proposed. From the result of the analysis, we may conclude that the students did not experience differential academic performance during their four years of studies.
