## **Abstract:**

In this paper random coincidence point results are proved for pair of commuting mapping defined on weakly compact separable subset of complete p-normed space. And then , use them to study the random best approximation in p-normed space with separability condition.

**Keywords** : p-normed space ,random coincidence point ,random best approximation.

## **1. Introduction:**

The well known best approximation theorems have been of importance in nonlinear functional analysis minmax theory , game theory ,...els. The calassiced approximation problem can be described as :

"Let A be a subspace of a normed linear space X , $x \in X$ , a best approximation to x from the elements of A would be a vector  $y \in A$  such that  $\|x - y\| = \text{dist}(x, A)$ [Singh 1997 ].

The early problems of best approximation theory like Ky-Fan' s theorem and Prolla's theorem [Singh 1997]depends on convexity properties which involve introducing a mapping with some hypotheses. These deals with Brosowski-Meinardus type [Singh 1997].

Fixed point and coincidence point theorems have been used at many places in approximation theory. One of them is proving the existence of best approximation. It is well known that random fixed point and ( coincidence ) theorems are stochastic generalization of classical fixed point and (coincidence )theorems that are known as deterministic results. Initially, the study of random fixed points into being by the prague school of probabilistic in 1950. In 1955 , Spacek proved firstly, existence of random fixed point for contraction mappings in separable complete metric space and then Han's [1957,1961] gave other results. In 1979 , Itohs extended Spacek's and Hans's results to multivalued contraction mappings . on the other hand ,Mukherjee [1966] gave a random version of schadner's fixed point theorem in atomic probability measure space and Bharucha-Reid [1972,1976] generalized these results in general probability measure spaces. Also Beg and Shanzad [1993,1994] proved some theorems about common fixed points and coincidence points for pair of compatible random mappings which are generalization for commuting random mappings.

This work was extended by Itoh [1979] for the existence of coincidence point of commuting random mappings defined on separable weakly compact subset of banach space. Recently , some papers about random fixed points and random coincidence points have been established such as Jhadd<sup>1</sup>and Salua<sup>2</sup>[2014] and Nashine\*[2008].

As applications of random fixed point theorems , Itoh[1979] represented a random solution of a differential equation in banach space. And ,Nashine [2010] proved random best approximation result.

In this paper , we give some results about random coincidence points which extending the previous work by Itoh[1979],Xu [1990] and Shahzad and Laitf[2000].

## **2.Preliminaries**

We need the following definitions and facts:

Let  $X$  be a linear space and  $\|\cdot\|_p$  be a real valued function on  $X$  with  $0 < p \leq 1$ . The pair  $(X, \|\cdot\|_p)$  is called a  $p$ -normed space if for all  $x, y$  in  $X$  and scalars  $\lambda$  :

i.  $\|x\|_p \geq 0$  and  $\|x\|_p = 0$  iff  $x = 0$

ii.  $\|\lambda x\|_p = |\lambda|^p \|x\|_p$

iii.  $\|x + y\|_p \leq \|x\|_p + \|y\|_p$

Every  $p$ -normed space  $X$  is a metric space with  $d_p(x, y) = \|x - y\|_p$ , for all  $x, y$  in  $X$ . If  $p = 1$ , we have the concept of a normed space [Nashine\* (2008)]. For examples of  $p$ -normed space see [Nashine 2006]. A  $p$ -normed space is not necessarily locally convex space. And the continuous dual  $X'$  of  $p$ -normed space  $X$  need not separate the point of  $X$  [Nashine\* 2008]. Throughout this paper  $X$  will be complete  $p$ -normed space whose dual separates the points of  $X$ . The following classes are needed

$2^X$  is the classes of all subsets of  $X$ ,

$CB(X)$  is the classes of all bounded closed subsets of  $X$ ,

$CD(X)$  is the classes of all nonempty closed subsets of  $X$ ,

$K(X)$  is the classes of all nonempty compact subsets of  $X$ ,

$K_w(X)$  is the classes of all nonempty weakly compact subsets of  $X$

$\bar{A}$  is the closure of a set  $A$ ,

$w-\bar{(A)}$  is the weakly closure of a set  $A$ .

Now, for any  $A, B$  in  $CB(X)$  the Hausdorff distance defined by

$$D(A, B) = \max \{ \sup_{a \in A} d(a, B), \sup_{b \in B} d(A, b) \}$$

where  $d(a, B) = \inf_{b \in B} \{ \|a - b\|_p \}$  [Zeidler 1986]. Let  $A$  be a subset of  $X$  for  $x_0 \in X$ , define the set  $p_A(x_0) = \{ z \in A : \|x_0 - z\|_p = d_p(x_0, A) \}$ , then an element  $z \in p_A(x_0)$  is called a best approximation of  $x_0$  in  $A$  [Nashine 2006].

The space  $X$  is said to be opial if for every sequence  $\langle x_n \rangle$  in  $X$ ,  $x_n \rightarrow x$  weakly as  $n \rightarrow \infty$  and  $x \neq y$  implying that

$\lim_{n \rightarrow \infty} \inf \|x_n - x\|_p \leq \lim_{n \rightarrow \infty} \inf \|x_n - y\|_p$ , for all  $y \in X$  [Nashine 2006]. The mapping  $G: A \rightarrow CB(X)$  is said to be multivalued demiclosed at  $y_0$  if the conditions  $x_n \in A, x_n \rightarrow x$  weakly,  $y_n \in Gx_n, y_n \rightarrow y$  strongly imply  $y \in Gx$  [Shahzad 2005]. A mapping  $h: A \rightarrow X$  is called affine if

$h(\lambda x + (1 - \lambda)y) = \lambda hx + (1 - \lambda)hy$  for all  $x, y \in A$  and  $0 < \lambda < 1$  [Shahzad 2004]. A mapping  $G: A \rightarrow CB(X)$  is called  $h$ -nonexpansive if  $D(Gx, Gy) \leq d(hx, hy)$  for any  $x, y \in A$  where  $h: A \rightarrow X$  [Shahzad 2004]. The pair  $\{ h, G \}$  is called commuting if  $hGx = Ghx$  for all  $x \in A$  [Shahzad 2005].

A set  $A$  is called starshaped if there exists at least one point  $q \in A$  such that  $kx + (1 - k)q \in A$  for all  $x \in A$  and  $0 \leq k \leq 1$ . In this case  $q$  is called the starcenter of  $A$  [Nashine 2006].

Now, let the pair  $(\Omega, \Sigma)$  be denote to the measurable space with  $\Sigma$  a sigma algebra of subsets of  $\Omega$ .

**Definition (2.1)** [Jhadd<sup>1</sup> and Salua<sup>2</sup> 2014]

A multivalued mapping  $F: \Omega \rightarrow CB(X)$  is called  $(\Sigma)$ -measurable if, for any open subset  $B$  of  $X$ ,  $F^{-1}(B) = \{ \omega \in \Omega : F(\omega) \cap B \neq \emptyset \} \in \Sigma$ .

**Definition (2.2) [Jhadd<sup>1</sup> and Salua<sup>2</sup>2014]**

A single mapping  $\delta: \Omega \rightarrow X$  is called a measurable selector of a multivalued measurable mapping  $F: \Omega \rightarrow CB(X)$  if  $\delta$  measurable and  $\delta(\omega) \in F(\omega)$  for each  $\omega \in \Omega$ .

**Definition (2.3) [Jhadd<sup>1</sup> and Salua<sup>2</sup>2014]**

A mapping  $h: \Omega \times X \rightarrow X$  (or  $G: \Omega \times X \rightarrow CB(X)$ ) is called a random operator if for any  $x \in X$ ,  $h(\cdot, x)$  (respectively  $G(\cdot, x)$ ) is measurable.

**Definition (2.4) [Shahzad and Latif 2000]**

A measurable mapping  $\delta: \Omega \rightarrow A$  is called random fixed point of a random operator  $h: \Omega \times X \rightarrow X$  (or  $G: \Omega \times X \rightarrow CB(X)$ ) if for every  $\omega \in \Omega$ ,  $\delta(\omega) = h(\omega, \delta(\omega))$  (respectively  $\delta(\omega) \in G(\omega, \delta(\omega))$ ).

**Definition (2.5) [Jhadd<sup>1</sup> and Salua<sup>2</sup>2014]**

A measurable mapping  $\delta: \Omega \rightarrow X$  is called random coincidence point of a random operator  $h: \Omega \times X \rightarrow X$  and  $G: \Omega \times A \rightarrow CB(X)$  if

$$h(\omega, \delta(\omega)) \in G(\omega, \delta(\omega)) \text{ for all } \omega \in \Omega.$$

**Definition (2.6) [Shahzad 2004]**

A random operator  $h: \Omega \times A \rightarrow X$  is called continuous (weakly continuous) if for each  $\omega \in \Omega$ ,  $h(\omega, \cdot)$  is continuous (weakly continuous).

**Definition (2.7) [Shahzad and Latif 2000]**

A random operator  $G: \Omega \times X \rightarrow CB(X)$  is said to be demiclosed if for each  $\omega \in \Omega$ ,  $G(\omega, \cdot): X \rightarrow CB(X)$  is demiclosed.

**Definition (2.8) [Shahzad and Latif 2000]**

A random operator  $h: \Omega \times X \rightarrow X$  is said to be affine if for each  $\omega \in \Omega$ ,  $h(\omega, \cdot): X \rightarrow X$  is affine.

**Definition (1.2)**

Let  $X$  be a  $p$ -normed space,  $A \subseteq X$  and  $G: \Omega \times X \rightarrow CB(X)$  be a multivalued random operator we say that  $A$  has property  $(P_1)$  if

- i.  $G: \Omega \times A \rightarrow CB(A)$
- ii.  $(1 - k_n)q + k_n G(\omega, x) \subseteq A$ , for some  $q \in A$  and a fixed real sequence  $\langle k_n \rangle$  converging to 1 and for each  $x \in A$  and for each  $\omega \in \Omega$ .

**Definition (1.3)**

Let  $X$  be a  $p$ -normed space,  $A \subseteq X$  and  $A$  has property  $(P_1)$  with respect to a random operator  $G: \Omega \times X \rightarrow CB(X)$ ,  $q \in A$  and sequence  $\langle k_n \rangle$ . A random mapping  $h: \Omega \times X \rightarrow X$  is said to be have property  $(P_2)$  on  $A$  with property  $(P_1)$  if

$$h(\omega, (1 - k_n)q + k_n G(\omega, x)) = (1 - k_n)h(\omega, q) + k_n h(\omega, G(\omega, x))$$

for all  $x \in A$  and  $n \in \mathbb{N}$  and  $\omega \in \Omega$ .

**3. Main results**

Shahzad and Latif [2000] prove the fixed point theorems for multivalued random mappings .

**Theorem (3.1)[ Shahzad and Latif 2000]**

Let  $(X, d)$  be a separable complete metric space,  $G : \Omega \times X \rightarrow CB(X)$  a multivalued random operator, and  $h : \Omega \times X \rightarrow X$  a continuous random operator such that  $G(\omega, X) \subset h(\omega, X)$  for each  $\omega \in \Omega$ . If  $G$  and  $h$  commute and for all  $x, y \in X$  and all  $\omega \in \Omega$ , we have  $D(G(\omega, x), G(\omega, y)) \leq k d(h(\omega, x), h(\omega, y))$ , where  $k \in (0, 1)$  and  $H$  is the Hausdorff metric on  $CB(X)$  induced by the metric  $d$ , then  $h$  and  $G$  have a random coincidence point .

**Theorem (3.2)**

Let  $A$  be a nonempty separable weakly compact subset of  $X$  has property  $(P_1)$  with respect to  $G$ ,  $h : \Omega \times A \rightarrow A$  be a continuous random mapping and  $G : \Omega \times A \rightarrow K(A)$  be an  $h$ -nonexpansive multivalued random mapping with properties  $(P_2)$ . If  $G$  and  $h$  are commute,  $(h-G)(\omega, \cdot)$  is demiclosed at 0 for all  $\omega \in \Omega$  and  $h(\omega, A) = A$ ,  $h(\omega, q) = q$  for all  $\omega \in \Omega$  then  $h$  and  $G$  have a random coincidence point .

**Proof :**

Since  $A$  has property  $(P_1)$  with respect to  $G$ , then for some  $q \in A$ , we get

$$(1-k_n)q + k_n G(\omega, x) \subseteq A, \text{ where } \lim_{n \rightarrow \infty} k_n = 1 (0 < k_n < 1), \text{ for each } x \in A \text{ and for each } \omega \in \Omega.$$

For each  $n$ , define the random mapping  $G_n$  by

$$G_n(\omega, x) = (1 - k_n)q + k_n G(\omega, x), \text{ for all } x \in A \text{ and all } \omega \in \Omega .$$

$$\text{We have, } G_n : \Omega \times A \rightarrow K(A).$$

since  $G$  is  $h$ -nonexpansive, then

$$\begin{aligned} D(G_n(\omega, x), G_n(\omega, y)) &= D[(1 - k_n)q + k_n G(\omega, x), (1 - k_n)q + \\ &\quad k_n G(\omega, y)] \\ &= (k_n)^p D(G(\omega, x), G(\omega, y)) \\ &\leq (k_n)^p d_p(h(\omega, x), h(\omega, y)) \end{aligned}$$

For all  $x, y \in A$  and all  $\omega \in \Omega$ . Therefore each  $G_n$  is a random  $h$ -contraction .

$$\text{Since } G(\omega, A) \subseteq A = h(\omega, A)$$

$$\text{Then for each } n, G_n(\omega, A) \subset A = h(\omega, A), \text{ for all } \omega \in \Omega .$$

Since  $h$  commute with  $G$ ,  $h(\omega, q) = q$  and  $h$  has property  $(P_2)$ , then

$$\begin{aligned} G_n(\omega, h(\omega, x)) &= (1 - k_n)q + k_n G(\omega, h(\omega, x)) \\ &= (1-k_n)h(\omega, q) + h(\omega, G(\omega, x)) \\ &= h(\omega, (1 - k_n)q + k_n G(\omega, x)) \\ &= h(\omega, G_n(\omega, x)) \end{aligned}$$

For all  $x \in A$  and all  $\omega \in \Omega$ . Hence each  $G_n$  commute with  $h$ .

Since  $A$  is separable and weakly compact, then the weak topology on  $A$  is a metric topology [Dunford 1958, p.434] which implies that  $A$  is Hausdorff [Körner 2015, p.25] then  $A$  is strongly closed, this implies  $A$  is a complete metric space [Kreyszing 1978, p.30]. Thus all the conditions of Theorem (3.1) are satisfied.

Therefore there is a measurable mapping  $\delta_n: \Omega \rightarrow A$  such that  $h(\omega, \delta_n(\omega)) \in G_n(\omega, \delta_n(\omega))$  for each  $\omega \in \Omega$ .

Now, for each  $n$  define  $Q_n: \Omega \rightarrow k_w(A)$  by  $Q_n(\omega) = \overline{\{h(\omega, \delta_i(\omega)) : i \geq n\}}$ .

Define  $Q: \Omega \rightarrow k_w(A)$  by  $Q(\omega) = \bigcap_{n=1}^{\infty} Q_n(\omega)$ .

Since  $A$  is complete  $p$ -normed space, then by Theorem (4.1) [Himmelberg 1975]  $Q$  is weakly measurable so  $Q$  has measurable selector  $\delta$  [Kuratowski and Ryll 1965].

By weak compactness of  $A$ , we have that a subsequence  $\{\delta_m(\omega)\}$  of  $\{\delta_n(\omega)\}$  converges weakly to  $\delta(\omega)$ . Also, by definition of  $G_m(\omega, x_m)$ , there is a  $e_m \in G(\omega, x_m)$  such that  $h(\omega, \delta_m(\omega)) = (1 - k_m)q + k_m e_m$

$$h(\omega, \delta_m(\omega)) = (1 - k_m)q + k_m e_m - e_m + e_m$$

$$h(\omega, \delta_m(\omega)) - e_m = (1 - k_m)(q - e_m)$$

Therefore,

$$\|h(\omega, \delta_m(\omega)) - e_m\|_p = (1 - k_m)^p \|q - e_m\|_p \rightarrow 0 \text{ as } m \rightarrow \infty.$$

Thus,  $\{h(\omega, \delta_m(\omega)) - e_m\}$  converges to zero.

since  $h(\omega, \delta_m(\omega)) - e_m \in (h - G)(\omega, \delta_m(\omega)) - e_m$  and  $(h - G)(\omega, \cdot)$  is demiclosed at zero, therefore  $h(\omega, \delta(\omega)) \in G(\omega, \delta(\omega))$ .

Hence  $h$  and  $G$  have a random coincidence point  $\delta: \Omega \rightarrow A$  such that for each  $\omega \in \Omega$ ,

$$h(\omega, \delta(\omega)) \in G(\omega, \delta(\omega)). \blacksquare$$

**Corollary (3.3):**

Suppose that  $A, G, h$  and  $q$  satisfy all the hypotheses of Theorem (1.5). If  $h$  is weakly continuous and  $X$  satisfies Opial's condition, then  $h$  and  $G$  have a random coincidence point.

Proof:

By lemma (3.2) [Bano, Khan and Latif 2003], the weak continuity and Opial's condition implies that demiclosedness of  $(h - G)$ .

So, by Theorem (1.5) the proof is complete. ■

**Corollary (3.4):**

Let  $A$  be a nonempty separable weakly compact subset of  $X$  which is starshaped with respect to  $q \in A$ ,  $h: \Omega \times A \rightarrow A$  be a continuous affine random operator and  $G: \Omega \times A \rightarrow K(A)$  be an  $h$ -nonexpansive multivalued random mapping. If  $G$  and  $h$  commute,  $(h - G)(\omega, \cdot)$  is demiclosed at 0 for all  $\omega \in \Omega$  and  $h(\omega, A) = A$ ,  $h(\omega, q) = q$  for all  $\omega \in \Omega$  then  $h$  and  $G$  have a random coincidence point.

**Corollary (3.5):**

Suppose that  $A, h, G$  and  $q$  satisfy all the hypotheses of Corollary (1.8). If  $h$  is weakly continuous and  $X$  satisfies Opial's condition, then  $h$  and  $G$  have a random coincidence point.

**Theorem (3.6)**

Suppose that  $A, h, G$  and  $q$  satisfy all the hypotheses of Theorem (1.5).

If for each  $\omega \in \Omega$ ,  $h(\omega, x) \in G(\omega, x)$  implies the existence of  $\lim_{n \rightarrow \infty} h^n(\omega, x)$ , then  $h$  and  $G$  have a common random fixed point.

**Proof**

By Theorem (1.5) there is measurable mapping  $\delta: \Omega \rightarrow A$  such that  $h(\omega, \delta(\omega)) \in G(\omega, \delta(\omega))$  for each  $\omega \in \Omega$ .  
 Now

$h^n(\omega, \delta(\omega)) = h^{n-1}(\omega, h(\omega, \delta(\omega))) \in h^{n-1}(\omega, G(\omega, \delta(\omega))) = G(\omega, h^{n-1}(\omega, \delta(\omega)))$  for each  $\omega \in \Omega$ . Letting  $n \rightarrow \infty$ , we obtain  $\delta(\omega) \in G(\omega, \delta(\omega))$ , where  $\delta(\omega) = \lim_{n \rightarrow \infty} h^n(\omega, \delta(\omega))$ . Clearly  $\delta(\omega) = h(\omega, \delta(\omega))$  for each  $\omega \in \Omega$ . Hence, for any  $\omega \in \Omega$ ,

$$\delta(\omega) = h(\omega, \delta(\omega)) \in G(\omega, \delta(\omega)) \quad \blacksquare$$

**Remark (3.7)**

If  $h = I$  (identity random mapping) in Theorem (1.5), Theorem (1.6), Corollary (1.7) and corollary (1.8) then  $G$  has a random fixed point.

**Theorem (3.8)**

Let  $X$  be a complete  $p$ -normed space. Let  $h: \Omega \times X \rightarrow X$  be a weakly continuous random mapping, and let  $G: \Omega \times X \rightarrow k(X)$  be an  $h$ -nonexpansive multivalued random mapping commute with  $h$ , such that  $G(\omega, x_0) = \{x_0\}$  for some  $x_0 \in X$  and for each  $\omega \in \Omega$ . Let  $A$  be a nonempty  $G(\omega, \cdot)$ -invariant subset of  $X$  and  $x_0 = h(\omega, x_0) \in G(\omega, x_0)$  for each  $\omega \in \Omega$ . Assume that  $p_A(x_0)$  is nonempty separable weakly compact and has property  $(P_1)$  with respect to  $G$  and  $h(\omega, q) = q$  for each  $\omega \in \Omega$ . Further assume that  $h(\omega, \cdot)$  is strongly continuous mapping for each

$\omega \in \Omega$  and has property (C) on  $p_A(x_0)$  with  $h(\omega, p_A(x_0)) = p_A(x_0)$  for each  $\omega \in \Omega$ . If  $(h-G)(\omega, \cdot)$  is demiclosed on  $p_A(x_0)$ , then there exists measurable map  $\delta: \Omega \rightarrow p_A(x_0)$  such that for each  $\omega \in \Omega$ ,  $h(\omega, \delta(\omega)) \in G(\omega, \delta(\omega))$ .

**Proof**

$$\text{Let } p_A(x_0) = M$$

Since  $M$  has property  $(P_1)$  with respect to  $G$ , then

$$(1-k_n)q + k_n G(\omega, x) \subseteq M \text{ for some } q \in M, \lim k_n = 1 (0 < k_n < 1), \text{ for each } x \in M \text{ and for each } \omega \in \Omega.$$

For each  $n$ , defined the random operator  $G_n$  by

$$G_n(\omega, x) = (1-k_n)q + k_n G(\omega, x), \text{ for all } x \in M \text{ and all } \omega \in \Omega.$$

Hence,  $G_n: \Omega \times M \rightarrow K(M)$ . since  $h$  is  $G$ -nonexpansive, then

$$\begin{aligned} \mathcal{D}(G_n(\omega, x), G_n(\omega, y)) &= \mathcal{D}((1-k_n)q + k_n G(\omega, x), (1-k_n)q + k_n G(\omega, y)) \\ &= (k_n)^p \mathcal{D}(G(\omega, x), G(\omega, y)) \\ &\leq (k_n)^p d_p(h(\omega, x), h(\omega, y)) \end{aligned}$$

For each  $x, y \in M$  and each  $\omega \in \Omega$ .

Therefore each  $G_n$  is a random  $h$ -contraction, and for each  $n$ ,  $G_n(\omega, M) \subset M = h(\omega, M)$ .

Since  $h$  commute with  $G$ ,  $h(\omega, q) = q$  for each  $\omega \in \Omega$  and  $h$  has property (C), then

$$\begin{aligned} G_n(\omega, h(\omega, x)) &= (1 - k_n)q + k_n G(\omega, h(\omega, x)) \\ &= (1 - k_n)h(\omega, q) + h(\omega, G(\omega, x)) \\ &= h(\omega, (1 - k_n)q + k_n G(\omega, x)) \\ &= h(\omega, G_n(\omega, x)) \end{aligned}$$

For all  $x \in M$  and all  $\omega \in \Omega$ . Hence each  $G_n$  commute with  $h$ .

Since  $M$  is separable and weakly compact, then the weak topology on  $M$  is a metric topology [Dunford 1958, p.434] which implies that  $M$  is hausdorff [Körner 2015, p.25] then  $M$  is strongly closed, this implies  $M$  is a complete metric space [Kreyszing 1978, p.30]. Thus all the conditions of Theorem (3.1) are satisfied.

Therefore there is a measurable map  $\delta_n: \Omega \rightarrow M$  such that  $h(\omega, \delta_n(\omega)) \in G_n(\omega, \delta_n(\omega))$  for each  $\omega \in \Omega$ .

For each  $n$  define  $Q_n: \Omega \rightarrow wk(M)$  by  $Q_n(\omega) = w - cl\{\delta_i(\omega): i \geq n\}$ ,

define  $Q: \Omega \rightarrow wk(M)$  by  $Q(\omega) = \bigcap_{n=1}^{\infty} Q_n(\omega)$ .

Since the weakly topology on  $M$  is metric topology, then  $Q$  is weak measurable and has measurable selector  $\delta$ . since  $M$  is weakly compact, then there is a subsequence  $\{\delta_m(\omega)\}$  of  $\{\delta_n(\omega)\}$  converges weakly to  $\delta(\omega)$ . also by definition of  $G_m(\omega, x_m)$ , there is a  $e_m \in G(\omega, x_m)$  such that  $h(\omega, \delta_m(\omega)) = (1 - k_m)q + k_m e_m$

$$= (1 - k_m)q + k_m e_m - e_m + e_m$$

$$h(\omega, \delta_m(\omega)) - e_m = (1 - k_m)(q - e_m)$$

$$\text{we get } \|h(\omega, \delta_m(\omega)) - e_m\|_p = (1 - k_m)^p \|q - e_m\|_p \rightarrow 0 \text{ as } m \rightarrow \infty.$$

Thus,  $\{h(\omega, \delta_m(\omega)) - e_m\}$  converges to zero .since

$h(\omega, \delta_m(\omega)) - e_m \in (h - G)(\omega, \delta_m(\omega)) - e_m$  and  $(h - G)(\omega, \cdot)$  is demiclosed at zero ,therefore  $h(\omega, \delta(\omega)) \in G(\omega, \delta(\omega))$ .

Hence  $h$  and  $G$  have a random coincidence point  $\delta: \Omega \rightarrow M$  such that for each  $\omega \in \Omega$ ,

$$h(\omega, \delta(\omega)) \in G(\omega, \delta(\omega)) \blacksquare$$
