Abstract

The purpose of this paper is to present some fixed point theorem in dislocated quasi metric space for expansive type mappings.

Mathematics Subject Classification: 54H25

Keywords: Dislocated Quasi Metric space, fixed point.

Introduction and Preliminaries:

It is well known that Banach Contraction mappings principle is one of the pivotal results of analysis. Generalizations of this principle have been obtained in several directions. Dass and Gupta [1] generalized Banach's Contraction principle in metric space. Also Rhoades [2] established a partial ordering for various definitions of contractive mappings. In 2005, Zeyada Salunke [4] proved some results on fixed point in dislocated quasimetric spaces. In 2005, Zeyada et al.[3] established a fixed point theorem in dislocated quasimetric spaces. In 2008, Aage and Salunke [4] proved some results on fixed point in dislocated quasimetric spaces. Recently, Isufati [5], proved fixed point theorem for contractive type condition with rational expression in dislocated quasimetric spaces. The following definitions will be needed in the sequel.

Definition 1.1(See [3]). Let X be a nonempty set, and let $d : X \times X \rightarrow [0, \infty)$ be a function, called a distance function. One needs the following conditions:

$$(M1) \quad d(x, x) = 0,$$

$$(M2) \quad d(x, y) = d(y, x) = 0, \text{ then } x = y$$

$$(M3) \quad d(x, y) = d(y, x),$$

$$(M4) \quad d(x, y) \leq d(x, z) + d(z, y),$$

$$(M4)' \quad d(x, y) \leq \max\{d(x, z), d(z, y)\}, \text{ for all } x, y, z \in X.$$

If d satisfies conditions (M1)-(M4), then it is called a metric on X . If d satisfies conditions (M1), (M2), and (M4), it is called a quasimetric on X . If it satisfies conditions (M2)-(M4) ((M2) and (M4)), it is called a dislocated metric (or simply d-metric) (a dislocated quasimetric (or simply dq-metric)) on X , respectively. If a metric d satisfies the strong triangle inequality (M)', then it is called an ultrametric.

Definition 1.2 (See [3]). A sequence $\{x_n\}_{n \in \mathbb{N}}$ in dq-metric space (dislocated quasimetric space) (X, d) is called a Cauchy sequence if, for given $\varepsilon > 0$, there exists $n_0 \in \mathbb{N}$ such that $d(x_m, x_n) < \varepsilon$ or $d(x_n, x_m) < \varepsilon$, that is, $\min\{d(x_m, x_n), d(x_n, x_m)\} < \varepsilon$ for all $m, n \geq n_0$.

Definition 1.3 (See [3]). A sequence $\{x_n\}_{n \in \mathbb{N}}$ in dq-metric space [d-metric space] is said to be d-converge to $x \in X$ provided that

$$\lim_{n \rightarrow \infty} d(x_n, x) = \lim_{n \rightarrow \infty} d(x, x_n) = 0 \tag{1.1}$$

In this case, x is called a dq-limit [d-limit] of $\{x_n\}$ and we write $x_n \rightarrow x$.

Definition 1.4 (See [3]). A dq-metric space (X, d) is called complete if every Cauchy sequence in it is a dq-convergent.

Main Results

In this paper, we prove some fixed point theorem for continuous mapping satisfying expansion condition in complete dq-metric space.

Theorem 2.1: Let (X, d) be a complete dislocated metric space and T a continuous mappings satisfying the following condition:

$$d(Tx, Ty) + \alpha \left[\frac{d(x, Ty) + d(y, Tx)}{1 + d(x, Ty)d(y, Tx)} \right] \geq \beta \frac{d(x, Tx)[1 + d(y, Ty)]}{1 + d(x, y)} + \gamma d(x, y) \tag{2.1}$$

For all $x, y \in X$, $x \neq y$, where $\alpha, \beta, \gamma \geq 0$ are real constants and $\beta + \gamma > 1 + 2\alpha$, $\gamma > 1 + \alpha$. Then T has a fixed point in X .

Proof: Choose $x_0 \in X$ be arbitrary, to define the iterative sequence $\{x_n\}_{n \in \mathbb{N}}$ as follows and $Tx_n = x_{n-1}$ for $n = 1, 2, 3, \dots$. Then, using (2.1) we obtain

$$\begin{aligned} d(Tx_{n+1}, Tx_{n+2}) + \alpha \left[\frac{d(x_{n+1}, Tx_{n+2}) + d(x_{n+2}, Tx_{n+1})}{1 + d(x_{n+1}, Tx_{n+2})d(x_{n+2}, Tx_{n+1})} \right] &\geq \beta \frac{d(x_{n+1}, Tx_{n+1})[1 + d(x_{n+2}, Tx_{n+2})]}{1 + d(x_{n+1}, x_{n+2})} \\ &+ \gamma d(x_{n+1}, x_{n+2}) \\ \Rightarrow d(x_n, x_{n+1}) + \alpha \left[\frac{d(x_{n+1}, x_{n+1}) + d(x_{n+2}, x_n)}{1 + d(x_{n+1}, x_{n+1})d(x_{n+2}, x_n)} \right] &\geq \beta \frac{d(x_{n+1}, x_n)[1 + d(x_{n+2}, x_{n+1})]}{1 + d(x_{n+1}, x_{n+2})} + \gamma d(x_{n+1}, x_{n+2}) \\ \Rightarrow d(x_n, x_{n+1}) + \alpha d(x_{n+2}, x_n) &\geq \beta d(x_n, x_{n+1}) + \gamma d(x_{n+1}, x_{n+2}) \\ \Rightarrow d(x_n, x_{n+1}) + \alpha d(x_n, x_{n+1}) + \alpha d(x_{n+1}, x_{n+2}) &\geq \beta d(x_n, x_{n+1}) + \gamma d(x_{n+1}, x_{n+2}) \\ \Rightarrow (1 + \alpha - \beta)d(x_n, x_{n+1}) &\geq (\gamma - \alpha)d(x_{n+1}, x_{n+2}) \end{aligned}$$

The last inequality gives

$$\begin{aligned} d(x_{n+1}, x_{n+2}) &\leq \left(\frac{1 + \alpha - \beta}{\gamma - \alpha} \right) d(x_n, x_{n+1}) \\ &\leq kd(x_n, x_{n+1}) \end{aligned} \tag{2.2}$$

Where $k = \frac{1 + \alpha - \beta}{\gamma - \alpha} < 1$. Hence by induction, we obtain

$$d(x_{n+1}, x_{n+2}) \leq k^{n+1} d(x_0, x_1)$$

Note that, for $m, n \in \mathbb{N}$ such that $m > n$ we have

$$\begin{aligned} d(x_m, x_n) &\leq d(x_m, x_{m-1}) + d(x_{m-1}, x_{m-2}) + \dots + d(x_{n+1}, x_n) \\ &\leq [k^{m-1} + k^{m-2} + \dots + k^n] d(x_0, x_1) \\ &\leq k^n (1 + k + k^2 + \dots + k^{m-n-1}) d(x_0, x_1) \\ &\leq k^n \sum_{r=0}^{\infty} k^r d(x_0, x_1) \\ &= \frac{k^n}{1 - k} d(x_0, x_1) \end{aligned} \tag{2.3}$$

Since $0 \leq k < 1$, then as $n \rightarrow \infty$, $k^n(1 - k)^{-1} \rightarrow 0$. Hence, $d(x_m, x_n) \rightarrow 0$ as $m, n \rightarrow \infty$. This forces that $\{x_n\}_{n \in \mathbb{N}}$ is a Cauchy sequence in X . But X is a complete dislocated metric space; hence, $\{x_n\}_{n \in \mathbb{N}}$ is d-converges. Call the d-limit $x^* \in X$. Then, $x_n \rightarrow x^*$ as $n \rightarrow \infty$. By continuity of T we have,

$$Tx^* = T\left(\lim_{n \rightarrow \infty} x_n\right) = \lim_{n \rightarrow \infty} Tx_n = \lim_{n \rightarrow \infty} x_{n-1} = x^* \tag{2.4}$$

That is, $Tx^* = x^*$; thus, T has a fixed point in X .

Uniqueness

Let y^* be another fixed point of T in X , then $Ty^* = y^*$ and $Tx^* = x^*$. now,

$$d(Tx^*, Ty^*) + \alpha \left[\frac{d(x^*, Ty^*) + d(y^*, Tx^*)}{1 + d(x^*, Ty^*)d(y^*, Tx^*)} \right] \geq \beta \frac{d(x^*, Tx^*)[1 + d(y^*, Ty^*)]}{1 + d(x^*, y^*)} + \gamma d(x^*, y^*) \quad (2.5)$$

This implies that

$$\begin{aligned} d(x^*, y^*) + \alpha \left[\frac{d(x^*, y^*) + d(y^*, x^*)}{1 + d(x^*, y^*)d(y^*, x^*)} \right] &\geq \beta \frac{d(x^*, x^*)[1 + d(y^*, y^*)]}{1 + d(x^*, y^*)} + \gamma d(x^*, y^*) \\ \Rightarrow d(x^*, y^*) + \frac{2\alpha d(x^*, y^*)}{1 + [d(x^*, y^*)]^2} &\geq \gamma d(x^*, y^*) \\ \Rightarrow d(x^*, y^*) + [d(x^*, y^*)]^3 + 2\alpha d(x^*, y^*) &\geq \gamma d(x^*, y^*) + \gamma [d(x^*, y^*)]^3 \\ \Rightarrow (1 + 2\alpha - \gamma)d(x^*, y^*) &\geq (\gamma - 1)[d(x^*, y^*)]^3 \\ d(x^*, y^*) &\leq \left(\frac{1 + 2\alpha - \gamma}{\gamma - 1} \right)^{\frac{1}{3}} d(x^*, y^*) \end{aligned} \quad (2.6)$$

This is true only when $d(x^*, x^*) = 0$. Similarly $d(y^*, x^*) = 0$. Hence $d(x^*, y^*) = d(y^*, x^*) = 0$ and so $x^* = y^*$. Hence, T has a unique fixed point in X .

Theorem 2.2: Let (X, d) be a complete dislocated metric space and T a surjective mapping satisfying the condition (2.1) for all $x, y \in X, x \neq y$, where $\alpha, \beta, \gamma \geq 0$ are real constants and $\beta + \gamma > 1 + 2\alpha, \gamma > 1 + \alpha$. Then, T has a fixed point in X .

Proof : Choose $x_0 \in X$ to be arbitrary, and define the iterative sequence $\{x_n\}_{n \in \mathbb{N}}$ as follows : $Tx_n = x_{n+1}$ for $n = 1, 2, 3, \dots$. Then, using (2.1), we obtain, sequence $\{x_n\}_{n \in \mathbb{N}}$ is a Cauchy sequence in X . But X is a complete dislocated metric space; hence $\{x_n\}_{n \in \mathbb{N}}$ is a d -converges. Call the d -limit $x^* \in X$. Then, $x_n \rightarrow x^*$ as $n \rightarrow \infty$.

Existence of fixed point

Since T is a surjective map, so there exists a point y in X , such that $x = Ty$. Consider

$$\begin{aligned} d(x_n, x) &= d(Tx_{n+1}, Ty) \\ &\geq -\alpha \left[\frac{d(x_{n+1}, Ty) + d(y, Tx_{n+1})}{1 + d(x_{n+1}, Ty)d(y, Tx_{n+1})} \right] + \beta \frac{d(x_{n+1}, Tx_{n+1})[1 + d(y, Ty)]}{1 + d(x_{n+1}, y)} + \gamma d(x_{n+1}, y) \end{aligned} \quad (2.7)$$

Taking $n \rightarrow \infty$, we get

$$\begin{aligned} d(x, x) &\geq -\alpha \left[\frac{d(x, x) + d(y, x)}{1 + d(x, x)d(y, x)} \right] + \beta \frac{d(x, x)[1 + d(y, x)]}{1 + d(x, y)} + \gamma d(x, y) \\ 0 &\geq -\alpha d(x, y) + \gamma d(x, y) \\ \Rightarrow (\gamma - \alpha)d(x, y) &\leq 0 \\ \Rightarrow d(x, y) &= 0 \text{ as } \gamma > \alpha \end{aligned} \quad (2.8)$$

Similarly, $d(y, x) = 0$. Hence $d(x, y) = d(y, x) = 0$

This implies $x = y$ and so $Tx = x$, that is x is fixed point of T .

Uniqueness

Let y^* be another fixed point of T in X , then $Ty^* = y^*$ and $Tx^* = x^*$. Now,

$$d(Tx^*, Ty^*) + \alpha \left[\frac{d(x^*, Ty^*) + d(y^*, Tx^*)}{1 + d(x^*, Ty^*)d(y^*, Tx^*)} \right] \geq \beta \frac{d(x^*, Tx^*)[1 + d(y^*, Ty^*)]}{1 + d(x^*, y^*)} + \gamma d(x^*, y^*)$$

This implies that

$$\begin{aligned}
 d(x^*, y^*) + \alpha \left[\frac{d(x^*, y^*) + d(y^*, x^*)}{1 + d(x^*, y^*)d(y^*, x^*)} \right] &\geq \beta \frac{d(x^*, x^*)[1 + d(y^*, y^*)]}{1 + d(x^*, y^*)} + \gamma d(x^*, y^*) \\
 \Rightarrow d(x^*, y^*) + \frac{2\alpha d(x^*, y^*)}{1 + [d(x^*, y^*)]^2} &\geq \gamma d(x^*, y^*) \\
 \Rightarrow d(x^*, y^*) + [d(x^*, y^*)]^3 + 2\alpha d(x^*, y^*) &\geq \gamma d(x^*, y^*) + \gamma [d(x^*, y^*)]^2 \\
 \Rightarrow (1 - 2\alpha - \gamma)d(x^*, y^*) &\geq (\gamma - 1)[d(x^*, y^*)]^3 \\
 \Rightarrow d(x^*, y^*) &\leq \left(\frac{1 + 2\alpha - \gamma}{\gamma - 1} \right)^{\frac{1}{3}} d(x^*, y^*) \tag{2.9}
 \end{aligned}$$

This is true only when $d(x^*, y^*) = 0$. Similarly, $d(y^*, x^*) = 0$. Hence $d(x^*, y^*) = d(y^*, x^*) = 0$ and so $x^* = y^*$. Hence T has a unique fixed point in X .

The proof is completed.
